INTRODUCTION

20 **Field of the Invention**

The field of this invention is chromoproteins, specifically fluorescent proteins.

Background of the Invention

Labeling is a tool for marking a protein, cell, or organism of interest and plays a prominent role in many biochemistry, molecular biology and medical diagnostic applications. A variety of different labels have
25 been developed, including radiolabels, chromolabels, fluorescent labels, chemiluminescent labels, etc. However, there is continued interest in the development of new labels. Of particular interest is the development of new protein labels, including chromo- and fluorescent protein labels.

Relevant Literature

U.S. Patents of interest include: 6,066,476; 6,020,192; 5,985,577; 5,976,796; 5,968,750; 5,968,738;
30 5,958,713; 5,919,445 and 5,874,304. Also of interest are: Matz, M.V., *et al.* (1999) *Nature Biotechnol.*, 17:969-973; Living Colors Red Fluorescent Protein (October 1999) *CLONTECHniques XIV* (4):2-6; Living

5

SUMMARY OF THE INVENTION

Anthozoa derived chromo/fluoroproteins and mutants thereof, as well as nucleic acid compositions encoding the same, are provided. Specific proteins of interest include chromo/fluoroproteins from the following specific anthozoa species: *Anemonia majano*, *Clavularia* sp., *Zoanthus* sp., *Zoanthus* sp., *Discosoma striata*, *Discosoma* sp. "red", *Anemonia sulcata*, *Discosoma* sp "green", *Discosoma* sp. "magenta", and mutants thereof. Also provided are fragments of the subject proteins and nucleic acids encoding the same, as well as antibodies to the subject proteins and transgenic cells and organisms. The subject protein and nucleic acid compositions find use in a variety of different applications. Finally, kits for use in such applications that include the subject proteins are provided.

Figure 8 provides the nucleotide and amino acid sequence of dgFP512.
Figure 9 provides the nucleotide and amino acid sequence of dmFP592.

25

DEFINITIONS

In accordance with the present invention there may be employed conventional molecular biology, microbiology, and recombinant DNA techniques within the skill of the art. Such techniques are explained fully in the literature. See, e.g., Maniatis, Fritsch & Sambrook, "Molecular Cloning: A Laboratory Manual" (1982); "DNA Cloning: A Practical Approach," Volumes I and II (D.N. Glover ed. 1985); "Oligonucleotide Synthesis" (M.J. Gait ed. 1984); "Nucleic Acid Hybridization" (B.D. Hames & S.J. Higgins eds. (1985)); "Transcription and Translation" (B.D. Hames & S.J. Higgins eds. (1984)); "Animal Cell Culture" (R.I. Freshney, ed. (1986)); "Immobilized Cells and Enzymes" (IRL Press, (1986)); B. Perbal, "A Practical Guide To Molecular Cloning" (1984).

35

A "vector" is a replicon, such as plasmid, phage or cosmid, to which another DNA segment may be attached so as to bring about the replication of the attached segment.

A "DNA molecule" refers to the polymeric form of deoxyribonucleotides (adenine, guanine, thymine, or cytosine) in either single stranded form or a double-stranded helix. This term refers only to the primary and secondary structure of the molecule, and does not limit it to any particular tertiary forms. Thus, this term includes double-stranded DNA found, inter alia, in linear DNA molecules (e.g., restriction fragments),
5 viruses, plasmids, and chromosomes.

A DNA "coding sequence" is a DNA sequence which is transcribed and translated into a polypeptide in vivo when placed under the control of appropriate regulatory sequences. The boundaries of the coding sequence are determined by a start codon at the 5' (amino) terminus and a translation stop codon at the 3' (carboxyl) terminus. A coding sequence can include, but is not limited to, prokaryotic sequences, cDNA from
10 eukaryotic mRNA, genomic DNA sequences from eukaryotic (e.g., mammalian) DNA, and synthetic DNA sequences. A polyadenylation signal and transcription termination sequence may be located 3' to the coding sequence.

As used herein, the term "hybridization" refers to the process of association of two nucleic acid strands to form an antiparallel duplex stabilized by means of hydrogen bonding between residues of the
15 opposite nucleic acid strands.

The term "oligonucleotide" refers to a short (under 100 bases in length) nucleic acid molecule.

"DNA regulatory sequences", as used herein, are transcriptional and translational control sequences, such as promoters, enhancers, polyadenylation signals, terminators, and the like, that provide for and/or regulate expression of a coding sequence in a host cell.

20 A "promoter sequence" is a DNA regulatory region capable of binding RNA polymerase in a cell and initiating transcription of a downstream (3' direction) coding sequence. For purposes of defining the present invention, the promoter sequence is bounded at its 3' terminus by the transcription initiation site and extends upstream (5' direction) to include the minimum number of bases or elements necessary to initiate transcription at levels detectable above background. Within the promoter sequence will be found a transcription initiation
25 site, as well as protein binding domains responsible for the binding of RNA polymerase. Eukaryotic promoters will often, but not always, contain "TATA" boxes and "CAT" boxes. Various promoters, including inducible promoters, may be used to drive the various vectors of the present invention.

As used herein, the terms "restriction endonucleases" and "restriction enzymes" refer to bacterial enzymes, each of which cut double-stranded DNA at or near a specific nucleotide sequence.

30 A cell has been "transformed" or "transfected" by exogenous or heterologous DNA when such DNA has been introduced inside the cell. The transforming DNA may or may not be integrated (covalently linked) into the genome of the cell. In prokaryotes, yeast, and mammalian cells for example, the transforming DNA may be maintained on an episomal element such as a plasmid. With respect to eukaryotic cells, a stably transformed cell is one in which the transforming DNA has become integrated into a chromosome so that it is
35 inherited by daughter cells through chromosome replication. This stability is demonstrated by the ability of the eukaryotic cell to establish cell lines or clones comprised of a population of daughter cells containing the transforming DNA. A "clone" is a population of cells derived from a single cell or common ancestor by

mitosis. A "cell line" is a clone of a primary cell that is capable of stable growth *in vitro* for many generations.

A "heterologous" region of the DNA construct is an identifiable segment of DNA within a larger DNA molecule that is not found in association with the larger molecule in nature. Thus, when the heterologous region encodes a mammalian gene, the gene will usually be flanked by DNA that does not flank the mammalian genomic DNA in the genome of the source organism. In another example, heterologous DNA includes coding sequence in a construct where portions of genes from two different sources have been brought together so as to produce a fusion protein product. Allelic variations or naturally-occurring mutational events do not give rise to a heterologous region of DNA as defined herein.

As used herein, the term "reporter gene" refers to a coding sequence attached to heterologous promoter or enhancer elements and whose product may be assayed easily and quantifiably when the construct is introduced into tissues or cells.

The amino acids described herein are preferred to be in the "L" isomeric form. The amino acid sequences are given in one-letter code (A: alanine; C: cysteine; D: aspartic acid; E: glutamic acid; F: phenylalanine; G: glycine; H: histidine; I: isoleucine; K: lysine; L: leucine; M: methionine; N: asparagine; P: proline; Q: glutamine; R: arginine; S: serine; T: threonine; V: valine; W: tryptophan; Y: tyrosine; X: any residue). NH_2 refers to the free amino group present at the amino terminus of a polypeptide. COOH refers to the free carboxy group present at the carboxy terminus of a polypeptide. In keeping with standard polypeptide nomenclature, *J Biol. Chem.*, 243 (1969), 3552-59 is used.

The term "immunologically active" defines the capability of the natural, recombinant or synthetic chromo/fluorescent protein, or any oligopeptide thereof, to induce a specific immune response in appropriate animals or cells and to bind with specific antibodies. As used herein, "antigenic amino acid sequence" means an amino acid sequence that, either alone or in association with a carrier molecule, can elicit an antibody response in a mammal. The term "specific binding," in the context of antibody binding to an antigen, is a term well understood in the art and refers to binding of an antibody to the antigen to which the antibody was raised, but not other, unrelated antigens.

As used herein the term "isolated" is meant to describe a polynucleotide, a polypeptide, an antibody, or a host cell that is in an environment different from that in which the polynucleotide, the polypeptide, the antibody, or the host cell naturally occurs.

DESCRIPTION OF THE SPECIFIC EMBODIMENTS

Anthozoa derived chromo/fluoroproteins and mutants thereof, as well as nucleic acid compositions encoding the same, are provided. Specific proteins of interest include chromo/fluoroproteins from the following specific anthozoa species: *Anemonia majano*, *Clavularia* sp., *Zoanthus* sp., *Zoanthus* sp., *Discosoma striata*, *Discosoma* sp. "red", *Anemonia sulcata*, *Discosoma* sp "green", *Discosoma* sp. "magenta", and mutants thereof. Also provided are fragments of the subject proteins and nucleic acids encoding the same, as well as antibodies to the subject proteins and transgenic cells and organisms. The subject protein and

nucleic acid compositions find use in a variety of different applications. Finally, kits for use in such applications that include the subject proteins are provided. In further describing the subject invention, the subject nucleic acid compositions will be described first, followed by a discussion of the subject protein compositions, antibody compositions and transgenic cells/organisms. Next a review of representative methods in which the subject proteins find use is provided.

Before the subject invention is further described, it is to be understood that the invention is not limited to the particular embodiments of the invention described below, as variations of the particular embodiments may be made and still fall within the scope of the appended claims. It is also to be understood that the terminology employed is for the purpose of describing particular embodiments, and is not intended to be limiting. Instead, the scope of the present invention will be established by the appended claims.

In this specification and the appended claims, the singular forms "a," "an," and "the" include plural reference unless the context clearly dictates otherwise. Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood to one of ordinary skill in the art to which this invention belongs.

NUCLEIC ACID COMPOSITIONS

As summarized above, the subject invention provides nucleic acid compositions encoding Anthozoa chromo- and fluoroproteins and mutants thereof, as well as fragments and homologues of these proteins. By nucleic acid composition is meant a composition comprising a sequence of DNA having an open reading frame that encodes an Anthozoa chromo/fluoro polypeptide of the subject invention, i.e., an Anthozoa chromo/fluoroprotein gene, and is capable, under appropriate conditions, of being expressed as an Anthozoa chromo/fluoro protein according to the subject invention. Also encompassed in this term are nucleic acids that are homologous, substantially similar or identical to the nucleic acids encoding proteins of the present invention. Thus, the subject invention provides genes and coding sequences thereof encoding the proteins of the subject invention, as well as homologs thereof. The subject nucleic acids are isolated, i.e., are present in other than their natural environment.

Specific nucleic acid compositions of interest are those that encode chromo/fluoroproteins (and mutants thereof) from the following specific anthozoa species: *Anemonia majano*, *Clavularia* sp., *Zoanthus* sp., *Zoanthus* sp., *Discosoma striata*, *Discosoma* sp. "red", *Anemonia sulcata*, *Discosoma* sp "green", *Discosoma* sp. "magenta." Each of these particular types of nucleic acid compositions of interest is now discussed in greater detail individually.

35 *Anemonia majano*

In these embodiments, the nucleic acid compositions are found in, or derived from a nucleic acid found in, an organism from Sub-class Zoantharia, often Order Actiniaria, more often Sub-order Endomyaria,

usually Family Actiniidae, and more usually Genus Anemonia, where in many embodiments, the organism is *Anemonia majano*, where the specific protein of interest from *Anemonia majano* is amFP486 (i.e., NFP-1), and homologues/mutants, e.g., Mut15, Mut32, thereof are of particular interest in many embodiments. The wild type cDNA coding sequence for amFP486 is provided in SEQ ID NO: 01.

5

Clavularia sp.

In these embodiments, the nucleic acids are found in or derived from nucleic acids found in organisms from Sub-class Alcyonaria, often Order Stolonifera, and more often the Family Clavulariidae, where the organism is usually from the Genus Clavularia, and in certain embodiments, the organism is *Clavularia sp.*, where the specific fluorescent protein from *Clavularia sp.* is cFP484 (i.e., NFP-2), and homologues/mutants, e.g., $\Delta 19$ cFP484 and $\Delta 38$ cFP484, thereof are of particular interest in many embodiments. The wild type cDNA coding sequence for cFP484 is provided in SEQ ID No: 03.

10

Zoanthus sp. I

In these embodiments, the nucleic acids are found in or derived from nucleic acids found in an organism from Sub-class Zoantharia, often Order Zoanthidea, more often Sub-order Brachycnemia, usually Family Zoanthidae, and more usually Genus Zoanthus, where in certain embodiments, the organism is *Zoanthus sp.*, where the specific fluorescent protein is zFP506 (i.e., NFP-3), and homologues/mutants, e.g., N65M variant of zFP506, thereof are of particular interest in many embodiments. The wild type cDNA coding sequence for zFP506 is provided in SEQ ID Nos: 05.

20

Zoanthus sp. II

In these embodiments, the nucleic acids are found in or derived from nucleic acids found in an organism from Sub-class Zoantharia, often Order Zoanthidea, more often Sub-order Brachycnemia, usually Family Zoanthidae, and more usually Genus Zoanthus, where in certain embodiments, the organism is *Zoanthus sp.*, where the specific fluorescent protein is zFP538 (NFP-4), and homologues/mutants, e.g., M128 variant of zFP538, thereof are of particular interest in many embodiments. The wild type cDNA coding sequence for zFP538 is provided in SEQ ID NO: 07.

25

Discosoma striata

In these embodiments, the nucleic acids are found in or derived from a nucleic acid found in an organism from Sub-class Zoantharia, often Order Corallimopharia, more often Family Discosomatidae, and usually Genus Discosoma, where in certain embodiments, the organism is *Discosoma striata*, where the specific fluorescent protein is dsFP483 (NFP-5), and homologues/mutants thereof are of particular interest in many embodiments. The wild type cDNA coding sequence for dsFP483 is provided in SEQ ID NO: 09.

30

35

Discosoma sp. "red"

In these embodiments, the nucleic acids are found in or derived from nucleic acids found in an organism from Sub-class Zoantharia, often Order Corallimopharia, more often Family Discosomatidae, and usually Genus *Discosoma*, where in certain embodiments, the organism is *Discosoma sp. "red"*, where the specific fluorescent protein is drFP583 (NFP-6), and homologues/mutants thereof, e.g., E5, E8, E5up, E5down, E57, AG4, AG4H, are of particular interest in many embodiments. The wild type cDNA coding sequence for drFP583 is provided in SEQ ID NO: 11.

Anemonia sulcata

In these embodiments, the nucleic acid is found in or derived from a nucleic acid found in an organism from Sub-class Zoantharia, often Order Actiniaria, more often Sub-Order Endomyaria, usually Family Actiniidae, and more usually Genus *Anemonia*, e.g., where in certain embodiments the organism is *Anemonia sulcata*, where the specific fluorescent protein asFP600 (NFP-7), and homologues/mutants thereof, e.g. Mut1, are of particular interest in many embodiments. The wild type cDNA coding sequence for asFP600 is provided in SEQ ID NO:14.

Discosoma sp "green"

In these embodiments, the nucleic acid is found in or derived from a nucleic acid found in an organism from Sub-class Zoantharia, often Order Corallimopharia, more often Family Discosomatidae, and usually Genus *Discosoma*, where in certain embodiments, the organism is *Discosoma sp. "green"*, where the specific fluorescent protein is dmFP592 (NFP-8), and homologues/mutants thereof are of particular interest in many embodiments. The wild type cDNA coding sequence for dgFP512 is provided in SEQ ID NO: 15.

Discosoma sp. "magenta"

In these embodiments, the nucleic acid is a nucleic acid found in or derived from a nucleic acid found in an organism from Sub-class Zoantharia, often Order Corallimopharia, more often Family Discosomatidae, and usually Genus *Discosoma* where in certain embodiments, the organism is *Discosoma sp. "magenta"*, where the specific fluorescent protein is dmFP592 (NFP-9), and homologues/mutants thereof are of particular interest in many embodiments. The wild type cDNA coding sequence for dmFP592 is provided in SEQ ID NO: 17.

In addition to the above described specific nucleic acid compositions, also of interest are homologues of the above sequences. With respect to homologues of the subject nucleic acids, the source of homologous genes may be any species of plant or animal. In certain embodiments, sequence similarity between homologues is at least about 20%, sometimes at least about 25 %, and may be 30 %, 35%, 40%, 50%, 60%, 70% or higher, including 75%, 80%, 85%, 90% and 95% or higher. Sequence similarity is calculated based on a reference sequence, which may be a subset of a larger sequence, such as a conserved motif, coding region, flanking region, etc. A reference sequence will usually be at least about 18 nt long, more usually at least

about 30 nt long, and may extend to the complete sequence that is being compared. Algorithms for sequence analysis are known in the art, such as BLAST, described in Altschul *et al.* (1990), *J. Mol. Biol.* 215:403-10 (using default settings, i.e. parameters $w=4$ and $T=17$). The sequences provided herein are essential for recognizing related and homologous nucleic acids in database searches. Of particular interest in certain embodiments are nucleic acids of substantially the same length as the nucleic acid identified as SEQ ID NOS:01 to 17, where by substantially the same length is meant that any difference in length does not exceed about 20 number %, usually does not exceed about 10 number % and more usually does not exceed about 5 number %; and have sequence identity to any of these sequences of at least about 90%, usually at least about 95% and more usually at least about 99% over the entire length of the nucleic acid. In many embodiments, the nucleic acids have a sequence that is substantially similar (i.e. the same as) or identical to the sequences of SEQ ID NOS: 01, 03, 05, 07, 09, 11, 13, 15, or 17. By substantially similar is meant that sequence identity will generally be at least about 60%, usually at least about 75% and often at least about 80, 85, 90, or even 95%.

Nucleic acids encoding mutants of the chromo/fluoroproteins of the invention are also provided. Mutant nucleic acids can be generated by random mutagenesis or targeted mutagenesis, using well-known techniques which are routine in the art.

In some embodiments, chromo- or fluorescent proteins encoded by nucleic acids encoding homologues or mutants have the same fluorescent properties as the wild-type fluorescent protein. In other embodiments, homologue or mutant nucleic acids encode chromo- or fluorescent proteins with altered spectral properties, as described in more detail herein.

Nucleic acids of the subject invention may be cDNA or genomic DNA or a fragment thereof. In certain embodiments, the nucleic acids of the subject invention include one or more of the open reading frame encoding specific fluorescent proteins and polypeptides, and introns, as well as adjacent 5' and 3' non-coding nucleotide sequences involved in the regulation of expression, up to about 20 kb beyond the coding region, but possibly further in either direction. The subject nucleic acids may be introduced into an appropriate vector for extrachromosomal maintenance or for integration into a host genome, as described in greater detail below.

The term "cDNA" as used herein is intended to include all nucleic acids that share the arrangement of sequence elements found in native mature mRNA species, where sequence elements are exons and 5' and 3' non-coding regions. Normally mRNA species have contiguous exons, with the intervening introns, when present, being removed by nuclear RNA splicing, to create a continuous open reading frame encoding the protein.

A genomic sequence of interest comprises the nucleic acid present between the initiation codon and the stop codon, as defined in the listed sequences, including all of the introns that are normally present in a native chromosome. It may further include 5' and 3' un-translated regions found in the mature mRNA. It may further include specific transcriptional and translational regulatory sequences, such as promoters, enhancers; *etc.*, including about 1 kb, but possibly more, of flanking genomic DNA at either the 5' or 3' end of the transcribed region. The genomic DNA may be isolated as a fragment of 100 kbp or smaller, and

substantially free of flanking chromosomal sequence. The genomic DNA flanking the coding region, either 3' or 5', or internal regulatory sequences as sometimes found in introns, contains sequences required for proper tissue and stage specific expression.

The nucleic acid compositions of the subject invention may encode all or a part of the subject chromo-
5 /fluorescent proteins. Double or single stranded fragments may be obtained from the DNA sequence by chemically synthesizing oligonucleotides in accordance with conventional methods, by restriction enzyme digestion, by PCR amplification, *etc.* For the most part, DNA fragments will be of at least 15 nt, usually at least 18 nt or 25 nt, and may be at least about 50 nt. In some embodiments, the subject nucleic acid molecules may be about 100 nt, about 200 nt, about 300 nt, about 400 nt, about 500 nt, about 600 nt, about 700 nt, or
10 about 720 nt in length. The subject nucleic acids may encode fragments of the subject proteins or the full-length proteins, e.g., the subject nucleic acids may encode polypeptides of about 25 aa, about 50 aa, about 75 aa, about 100 aa, about 125 aa, about 150 aa, about 200 aa, about 210 aa, about 220 aa, about 230 aa, or about 240 aa, up to the entire protein.

The subject nucleic acids are isolated and obtained in substantial purity, generally as other than an
15 intact chromosome. Usually, the DNA will be obtained substantially free of other nucleic acid sequences that do not include a nucleic acid of the subject invention or fragment thereof, generally being at least about 50%, usually at least about 90% pure and are typically "recombinant", *i.e.* flanked by one or more nucleotides with which it is not normally associated on a naturally occurring chromosome.

The subject polynucleotides (*e.g.*, a polynucleotide having a sequence of SEQ ID NOS: 01 to 17 *etc.*),
20 the corresponding cDNA, the full-length gene and constructs of the subject polynucleotides are provided. These molecules can be generated synthetically by a number of different protocols known to those of skill in the art. Appropriate polynucleotide constructs are purified using standard recombinant DNA techniques as described in, for example, Sambrook *et al.*, *Molecular Cloning: A Laboratory Manual, 2nd Ed.*, (1989) Cold Spring Harbor Press, Cold Spring Harbor, NY, and under current regulations described in United States Dept.
25 of HHS, National Institute of Health (NIH) Guidelines for Recombinant DNA Research.

Also provided are nucleic acids that encode fusion proteins of the subject proteins, or fragments thereof, which are fused to a second protein, *e.g.*, a degradation sequence, a signal peptide, *etc.* Fusion proteins may comprise a subject polypeptide, or fragment thereof, and a non-anthozoa polypeptide ("the fusion partner") fused in-frame at the N-terminus and/or C-terminus of the subject polypeptide. Fusion
30 partners include, but are not limited to, polypeptides that can bind antibody specific to the fusion partner (*e.g.*, epitope tags); antibodies or binding fragments thereof; polypeptides that provide a catalytic function or induce a cellular response; ligands or receptors or mimetics thereof; and the like. In such fusion proteins, the fusion partner is generally not naturally associated with the subject anthozoa portion of the fusion protein, and is typically not an anthozoa protein or derivative/fragment thereof, *i.e.*, it is not found in Anthozoa species.

Also provided are constructs comprising the subject nucleic acids inserted into a vector, where such
35 constructs may be used for a number of different applications, including propagation, protein production, *etc.* Viral and non-viral vectors may be prepared and used, including plasmids. The choice of vector will depend

on the type of cell in which propagation is desired and the purpose of propagation. Certain vectors are useful for amplifying and making large amounts of the desired DNA sequence. Other vectors are suitable for expression in cells in culture. Still other vectors are suitable for transfer and expression in cells in a whole animal or person. The choice of appropriate vector is well within the skill of the art. Many such vectors are available commercially. To prepare the constructs, the partial or full-length polynucleotide is inserted into a vector typically by means of DNA ligase attachment to a cleaved restriction enzyme site in the vector. Alternatively, the desired nucleotide sequence can be inserted by homologous recombination *in vivo*. Typically this is accomplished by attaching regions of homology to the vector on the flanks of the desired nucleotide sequence. Regions of homology are added by ligation of oligonucleotides, or by polymerase chain reaction using primers comprising both the region of homology and a portion of the desired nucleotide sequence, for example.

Also provided are expression cassettes or systems that find use in, among other applications, the synthesis of the subject proteins. For expression, the gene product encoded by a polynucleotide of the invention is expressed in any convenient expression system, including, for example, bacterial, yeast, insect, amphibian and mammalian systems. Suitable vectors and host cells are described in U.S. Patent No. 5,654,173. In the expression vector, a subject polynucleotide, e.g., as set forth in SEQ ID NOS:01 to 17, is linked to a regulatory sequence as appropriate to obtain the desired expression properties. These regulatory sequences can include promoters (attached either at the 5' end of the sense strand or at the 3' end of the antisense strand), enhancers, terminators, operators, repressors, and inducers. The promoters can be regulated or constitutive. In some situations it may be desirable to use conditionally active promoters, such as tissue-specific or developmental stage-specific promoters. These are linked to the desired nucleotide sequence using the techniques described above for linkage to vectors. Any techniques known in the art can be used. In other words, the expression vector will provide a transcriptional and translational initiation region, which may be inducible or constitutive, where the coding region is operably linked under the transcriptional control of the transcriptional initiation region, and a transcriptional and translational termination region. These control regions may be native to the subject species from which the subject nucleic acid is obtained, or may be derived from exogenous sources.

Expression vectors generally have convenient restriction sites located near the promoter sequence to provide for the insertion of nucleic acid sequences encoding heterologous proteins. A selectable marker operative in the expression host may be present. Expression vectors may be used for, among other things, the production of fusion proteins, as described above.

Expression cassettes may be prepared comprising a transcription initiation region, the gene or fragment thereof, and a transcriptional termination region. Of particular interest is the use of sequences that allow for the expression of functional epitopes or domains, usually at least about 8 amino acids in length, more usually at least about 15 amino acids in length, to about 25 amino acids, and up to the complete open reading frame of the gene. After introduction of the DNA, the cells containing the construct may be selected by means of a selectable marker, the cells expanded and then used for expression.

The above described expression systems may be employed with prokaryotes or eukaryotes in accordance with conventional ways, depending upon the purpose for expression. For large scale production of the protein, a unicellular organism, such as *E. coli*, *B. subtilis*, *S. cerevisiae*, insect cells in combination with baculovirus vectors, or cells of a higher organism such as vertebrates, e.g. COS 7 cells, HEK 293, CHO, *Xenopus* Oocytes, etc., may be used as the expression host cells. In some situations, it is desirable to express the gene in eukaryotic cells, where the expressed protein will benefit from native folding and post-translational modifications. Small peptides can also be synthesized in the laboratory. Polypeptides that are subsets of the complete protein sequence may be used to identify and investigate parts of the protein important for function.

Specific expression systems of interest include bacterial, yeast, insect cell and mammalian cell derived expression systems. Representative systems from each of these categories is are provided below:

Bacteria. Expression systems in bacteria include those described in Chang *et al.*, *Nature* (1978) 275:615; Goeddel *et al.*, *Nature* (1979) 281:544; Goeddel *et al.*, *Nucleic Acids Res.* (1980) 8:4057; EP 0 036,776; U.S. Patent No. 4,551,433; DeBoer *et al.*, *Proc. Natl. Acad. Sci. (USA)* (1983) 80:21-25; and Siebenlist *et al.*, *Cell* (1980) 20:269.

Yeast. Expression systems in yeast include those described in Hinnen *et al.*, *Proc. Natl. Acad. Sci. (USA)* (1978) 75:1929; Ito *et al.*, *J. Bacteriol.* (1983) 153:163; Kurtz *et al.*, *Mol. Cell. Biol.* (1986) 6:142; Kunze *et al.*, *J. Basic Microbiol.* (1985) 25:141; Gleeson *et al.*, *J. Gen. Microbiol.* (1986) 132:3459; Roggenkamp *et al.*, *Mol. Gen. Genet.* (1986) 202:302; Das *et al.*, *J. Bacteriol.* (1984) 158:1165; De Louvencourt *et al.*, *J. Bacteriol.* (1983) 154:737; Van den Berg *et al.*, *Bio/Technology* (1990) 8:135; Kunze *et al.*, *J. Basic Microbiol.* (1985) 25:141; Cregg *et al.*, *Mol. Cell. Biol.* (1985) 5:3376; U.S. Patent Nos. 4,837,148 and 4,929,555; Beach and Nurse, *Nature* (1981) 300:706; Davidow *et al.*, *Curr. Genet.* (1985) 10:380; Gaillardin *et al.*, *Curr. Genet.* (1985) 10:49; Ballance *et al.*, *Biochem. Biophys. Res. Commun.* (1983) 112:284-289; Tilburn *et al.*, *Gene* (1983) 26:205-221; Yelton *et al.*, *Proc. Natl. Acad. Sci. (USA)* (1984) 81:1470-1474; Kelly and Hynes, *EMBO J.* (1985) 4:475479; EP 0 244,234; and WO 91/00357.

Insect Cells. Expression of heterologous genes in insects is accomplished as described in U.S. Patent No. 4,745,051; Friesen *et al.*, "The Regulation of Baculovirus Gene Expression", in: *The Molecular Biology Of Baculoviruses* (1986) (W. Doerfler, ed.); EP 0 127,839; EP 0 155,476; and Vlak *et al.*, *J. Gen. Virol.* (1988) 69:765-776; Miller *et al.*, *Ann. Rev. Microbiol.* (1988) 42:177; Carbonell *et al.*, *Gene* (1988) 73:409; Maeda *et al.*, *Nature* (1985) 315:592-594; Lebacqz-Verheyden *et al.*, *Mol. Cell. Biol.* (1988) 8:3129; Smith *et al.*, *Proc. Natl. Acad. Sci. (USA)* (1985) 82:8844; Miyajima *et al.*, *Gene* (1987) 58:273; and Martin *et al.*, *DNA* (1988) 7:99. Numerous baculoviral strains and variants and corresponding permissive insect host cells from hosts are described in Luckow *et al.*, *Bio/Technology* (1988) 6:47-55, Miller *et al.*, *Generic Engineering* (1986) 8:277-279, and Maeda *et al.*, *Nature* (1985) 315:592-594.

Mammalian Cells. Mammalian expression is accomplished as described in Dijkema *et al.*, *EMBO J.* (1985) 4:761; Gorman *et al.*, *Proc. Natl. Acad. Sci. (USA)* (1982) 79:6777; Boshart *et al.*, *Cell* (1985) 41:521 and U.S. Patent No. 4,399,216. Other features of mammalian expression are facilitated as described

in Ham and Wallace, *Meth. Enz.* (1979) 58:44, Barnes and Sato, *Anal. Biochem.* (1980) 102:255, U.S. Patent Nos. 4,767,704, 4,657,866, 4,927,762, 4,560,655, WO 90/103430, WO 87/00195, and U.S. RE 30,985.

When any of the above host cells, or other appropriate host cells or organisms, are used to replicate and/or express the polynucleotides or nucleic acids of the invention, the resulting replicated nucleic acid, RNA, expressed protein or polypeptide, is within the scope of the invention as a product of the host cell or organism. The product is recovered by any appropriate means known in the art.

Once the gene corresponding to a selected polynucleotide is identified, its expression can be regulated in the cell to which the gene is native. For example, an endogenous gene of a cell can be regulated by an exogenous regulatory sequence inserted into the genome of the cell at location sufficient to at least enhance expressed of the gene in the cell. The regulatory sequence may be designed to integrate into the genome via homologous recombination, as disclosed in U.S. Patent Nos. 5,641,670 and 5,733,761, the disclosures of which are herein incorporated by reference, or may be designed to integrate into the genome via non-homologous recombination, as described in WO 99/15650, the disclosure of which is herein incorporated by reference. As such, also encompassed in the subject invention is the production of the subject proteins without manipulation of the encoding nucleic acid itself, but instead through integration of a regulatory sequence into the genome of cell that already includes a gene encoding the desired protein, as described in the above incorporated patent documents.

Also provided are homologs of the subject nucleic acids. Homologs are identified by any of a number of methods. A fragment of the provided cDNA may be used as a hybridization probe against a cDNA library from the target organism of interest, where low stringency conditions are used. The probe may be a large fragment, or one or more short degenerate primers. Nucleic acids having sequence similarity are detected by hybridization under low stringency conditions, for example, at 50°C and 6×SSC (0.9 M sodium chloride/0.09 M sodium citrate) and remain bound when subjected to washing at 55°C in 1×SSC (0.15 M sodium chloride/0.015 M sodium citrate). Sequence identity may be determined by hybridization under stringent conditions, for example, at 50°C or higher and 0.1×SSC (15 mM sodium chloride/0.15 mM sodium citrate). Nucleic acids having a region of substantial identity to the provided sequences, e.g. allelic variants, genetically altered versions of the gene, etc., bind to the provided sequences under stringent hybridization conditions. By using probes, particularly labeled probes of DNA sequences, one can isolate homologous or related genes.

Also of interest are promoter elements of the subject genomic sequences, where the sequence of the 5' flanking region may be utilized for promoter elements, including enhancer binding sites, e.g., that provide for regulation of expression in cells/tissues where the subject proteins gene are expressed.

Also provided are small DNA fragments of the subject nucleic acids, which fragments are useful as primers for PCR, hybridization screening probes, etc. Larger DNA fragments, i.e., greater than 100 nt are useful for production of the encoded polypeptide, as described in the previous section. For use in geometric amplification reactions, such as geometric PCR, a pair of primers will be used. The exact composition of the primer sequences is not critical to the invention, but for most applications the primers will hybridize to the subject sequence under stringent conditions, as known in the art. It is preferable to choose a pair of primers

that will generate an amplification product of at least about 50 nt, preferably at least about 100 nt. Algorithms for the selection of primer sequences are generally known, and are available in commercial software packages. Amplification primers hybridize to complementary strands of DNA, and will prime towards each other.

5 The DNA may also be used to identify expression of the gene in a biological specimen. The manner in which one probes cells for the presence of particular nucleotide sequences, as genomic DNA or RNA, is well established in the literature. Briefly, DNA or mRNA is isolated from a cell sample. The mRNA may be amplified by RT-PCR, using reverse transcriptase to form a complementary DNA strand, followed by polymerase chain reaction amplification using primers specific for the subject DNA sequences. Alternatively,
10 the mRNA sample is separated by gel electrophoresis, transferred to a suitable support, e.g. nitrocellulose, nylon, etc., and then probed with a fragment of the subject DNA as a probe. Other techniques, such as oligonucleotide ligation assays, *in situ* hybridizations, and hybridization to DNA probes arrayed on a solid chip may also find use. Detection of mRNA hybridizing to the subject sequence is indicative of Anthozoa protein gene expression in the sample.

15 The subject nucleic acids, including flanking promoter regions and coding regions, may be mutated in various ways known in the art to generate targeted changes in promoter strength, sequence of the encoded protein, properties of the encoded protein, including fluorescent properties of the encoded protein, etc. The DNA sequence or protein product of such a mutation will usually be substantially similar to the sequences provided herein, e.g. will differ by at least one nucleotide or amino acid, respectively, and may differ by at
20 least two but not more than about ten nucleotides or amino acids. The sequence changes may be substitutions, insertions, deletions, or a combination thereof. Deletions may further include larger changes, such as deletions of a domain or exon, e.g. of stretches of 10, 20, 50, 75, 100, 150 or more aa residues. Techniques for *in vitro* mutagenesis of cloned genes are known. Examples of protocols for site specific mutagenesis may be found in Gustin *et al.* (1993), *Biotechniques* 14:22; Barany (1985), *Gene* 37:111-23; Colicelli *et al.* (1985), *Mol. Gen.*
25 *Genet.* 199:537-9; and Prentki *et al.* (1984), *Gene* 29:303-13. Methods for site specific mutagenesis can be found in Sambrook *et al.*, *Molecular Cloning: A Laboratory Manual*, CSH Press 1989, pp. 15.3-15.108; Weiner *et al.* (1993), *Gene* 126:35-41; Sayers *et al.* (1992), *Biotechniques* 13:592-6; Jones and Winistorfer (1992), *Biotechniques* 12:528-30; Barton *et al.* (1990), *Nucleic Acids Res* 18:7349-55; Marotti and Tomich (1989), *Gene Anal. Tech.* 6:67-70; and Zhu (1989), *Anal Biochem* 177:120-4. Such mutated nucleic acid
30 derivatives may be used to study structure-function relationships of a particular chromo/ fluorescent protein, or to alter properties of the protein that affect its function or regulation.

 Of particular interest in many embodiments is the following specific mutation protocol, which protocol finds use in mutating chromoproteins into fluorescent mutants. In this protocol, the sequence of the candidate protein is aligned with the amino acid sequence of *Aequorea victoria* wild type GFP, according to
35 the protocol reported in Matz *et al.*, "Fluorescent proteins from nonbioluminescent Anthozoa species," *Nature Biotechnology* (October 1999) 17: 969-973. Residue 148 of the chromoprotein is identified and then changed to Ser, e.g., by site directed mutagenesis, which results in the production of a fluorescent mutant of the wild

type chromoprotein. See e.g., NFP-7 described below, which wild type protein is a chromoprotein that is mutated into a fluorescent protein by substitution of Ser for the native Ala residue at position 148.

Also of interest are humanized versions of the subject nucleic acids. As used herein, the term "humanized" refers to changes made to the a nucleic acid sequence to optimize the codons for expression of the protein in human cells (Yang et al., *Nucleic Acids Research* 24 (1996), 4592-4593).

In many embodiments, proteins found in bioluminescent species are not included within the scope of the invention. In certain embodiments, the GFP homolog and nucleic acids encoding the same from *Renilla reniformis* are not included within the scope of the subject invention.

10 PROTEIN/POLYPEPTIDE COMPOSITIONS

Also provided by the subject invention are Anthozoa chromo- and fluorescent proteins and mutants thereof, as well as polypeptide compositions related thereto. As the subject proteins are chromoproteins, they are colored proteins, which may be fluorescent, low or non- fluorescent. As used herein, the terms chromoprotein and fluorescent protein do not include luciferases, such as *Renilla* luciferase. The term polypeptide composition as used herein refers to both the full-length protein, as well as portions or fragments thereof. Also included in this term are variations of the naturally occurring protein, where such variations are homologous or substantially similar to the naturally occurring protein, and mutants of the naturally occurring proteins, as described in greater detail below. The subject polypeptides are present in other than their natural environment.

In many embodiments, the subject proteins have an absorbance maximum ranging from about 300 to 700, usually from about 350 to 650 and more usually from about 400 to 600 nm. Where the subject proteins are fluorescent proteins, by which is meant that they can be excited at one wavelength of light following which they will emit light at another wavelength, the excitation spectra of the subject proteins typically ranges from about 300 to 700, usually from about 350 to 650 and more usually from about 400 to 600 nm while the emission spectra of the subject proteins typically ranges from about 400 to 800, usually from about 425 to 775 and more usually from about 450 to 750 nm. The subject proteins generally have a maximum extinction coefficient that ranges from about 10,000 to 50,000 and usually from about 15,000 to 45,000. The subject proteins typically range in length from about 150 to 300 and usually from about 200 to 300 amino acid residues, and generally have a molecular weight ranging from about 15 to 35 kDa, usually from about 17.5 to 32.5 kDa.

In certain embodiments, the subject proteins are bright, where by bright is meant that the chromoproteins and their fluorescent mutants can be detected by common methods (e.g., visual screening, spectrophotometry, spectrofluorometry, fluorescent microscopy, by FACS machines, etc.) Fluorescence brightness of particular fluorescent proteins is determined by its quantum yield multiplied by maximal extinction coefficient. Brightness of a chromoproteins may be expressed by its maximal extinction coefficient.

In certain embodiments, the subject proteins fold rapidly following expression in the host cell. By rapidly folding is meant that the proteins achieve their tertiary structure that gives rise to their chromo- or

fluorescent quality in a short period of time. In these embodiments, the proteins fold in a period of time that generally does not exceed about 3 days, usually does not exceed about 2 days and more usually does not exceed about 1 day.

Specific proteins of interest are chromo/fluoroproteins (and mutants thereof) from the following specific anthozoa species: *Anemonia majano*, *Clavularia* sp., *Zoanthus* sp., *Zoanthus* sp., *Discosoma striata*, *Discosoma* sp. "red", *Anemonia sulcata*, *Discosoma* sp "green", *Discosoma* sp. "magenta." Each of these particular types of polypeptide compositions of interest is now discussed in greater detail individually.

Anemonia majano

The proteins of this embodiment have an absorbance maximum ranging from about 250 to 650, usually from about 400 to 500 and more usually from about 440 to 480 nm while the emission maximum typically ranges from about 270 to 670, usually from about 420 to 520 and more usually from about 460 to 500 nm. The subject proteins typically range in length from about 200 to 250, usually from about 210 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest in many embodiments is amFP486 (NFP-1), which has an amino acid sequence as shown in SEQ ID NO:02. Also of interest are mutants of this sequence, e.g., Mut15, Mut32, and the like.

Clavularia sp.

The proteins of this embodiment have an absorbance maximum that typically ranges from about 250 to 650, usually from about 400 to 500 and more usually from about 440 to 480 nm and an emission maximum that typically ranges from about 270 to 670, usually from about 420 to 520 and more usually from about 460 to 500 nm, where the subject proteins typically range in length from about 225 to 300, usually from about 250 to 275 amino acid residues, and generally have a molecular weight ranging from about 25 to 35, usually from about 27.50 to 32.50 kDa. Of particular interest is the cFP484 protein having the sequence shown in SEQ ID NO:04, as well as mutants thereof, e.g., $\Delta 19$ cFP484 and $\Delta 38$ cFP484 (NFP-2), and the like.

Zoanthus sp I.

The proteins of this embodiment have an absorbance maximum that typically ranges from about 300 to 700, usually from about 450 to 550 and more usually from about 480 to 510 nm and an emission maximum that typically ranges from about 320 to 720, usually from about 470 to 570 and more usually from about 500 to 530 nm. The subject proteins typically range in length from about 200 to 250, usually from about 220 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest is the protein zFP506 (NFP-3) which has an amino acid sequence as shown in SEQ ID NO:06, as well as mutants of this protein, e.g., the N65M variant, and the like.

Zoanthus sp. II

The proteins of this embodiment have an excitation maximum that typically ranges from about 300 to 650, usually from about 475 to 575 and more usually from about 500 to 550 nm and an emission maximum that typically ranges from about 310 to 660, usually from about 485 to 585 and more usually from about 510 to 560 nm. The subject proteins typically range in length from about 200 to 250, usually from about 220 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest is the protein sFP538 (NFP-4) which has an amino acid sequence as shown in SEQ ID NO:08, as well as mutants thereof, e.g., the M128 variant, etc.

10 *Discosoma striata*

The proteins of this embodiment have an excitation maximum that typically ranges from about 240 to 640, usually from about 500 to 600 and more usually from about 530 to 560 nm and an emission maximum that typically ranges from about 280 to 680, usually from about 540 to 640 and more usually from about 570 to 600 nm. The subject proteins typically range in length from about 200 to 250, usually from about 220 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest in many embodiments is the protein dsFP483 (NFP-5) which has an amino acid sequence as shown in SEQ ID NO:10, as well as mutants thereof.

Discosoma sp. "red"

20 The proteins of this embodiment have an absorbance maximum that typically ranges from about 250 to 750, usually from about 500 to 600 and more usually from about 540 to 580 nm and have an emission maximum that typically ranges from about 275 to 775, usually from about 525 to 625 and more usually from about 565 to 605 nm. The subject proteins typically range in length from about 200 to 250, usually from about 220 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest is the drFP583 (NFP-6) protein that has an amino acid sequence as shown in SEQ ID NO:12, as well as mutants thereof, e.g., E5, E8, E5up, E5down, E57, AG4, AG4H, etc.

Anemonia sulcata

30 The proteins of this embodiment have an absorbance maximum that typically ranges from about 370 to 770, usually from about 520 to 620 and more usually from about 560 to 580 nm and an emission maximum that typically ranges from about 395 to 795, usually from about 545 to 645 and more usually from about 585 to 605 nm. The subject proteins typically range in length from about 200 to 250, usually from about 220 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest is the asFP600 (NFP-7) protein that has an amino acid sequence as shown in SEQ ID NO:14, as well as mutants thereof, e.g. Mut1, etc.

Discosoma sp. "green"

The proteins of this embodiment have an absorbance maximum that typically ranges from about 300 to 700, usually from about 450 to 650 and more usually from about 490 to 510 nm and an emission maximum that typically ranges from about 310 to 710, usually from about 460 to 660 and more usually from about 500 to 520 nm. The subject proteins typically range in length from about 200 to 250, usually from about 220 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest is the dgFP512 protein (NFP-8) protein that has an amino acid sequence as shown in SEQ ID NO:16, as well as mutants thereof.

10 *Discosoma sp. "magenta"*

The proteins of this embodiment have an absorbance maximum that typically ranges from about 375 to 775, usually from about 525 to 625 and more usually from about 560 to 590 nm and an emission maximum that typically ranges from about 395 to 795, usually from about 545 to 645 and more usually from about 580 to 610 nm. The subject proteins typically range in length from about 200 to 250, usually from about 220 to 240 amino acid residues, and generally have a molecular weight ranging from about 20 to 30, usually from about 22.50 to 27.50 kDa. Of particular interest is the dmFP592 (NFP-9) protein that has an amino acid sequence as shown in SEQ ID NO:18, as well as mutants thereof.

Homologs or proteins (or fragments thereof) that vary in sequence from the above provided specific amino acid sequences of the subject invention, i.e., SEQ ID NOS: 02 to 18, are also provided. By homolog is meant a protein having at least about 10%, usually at least about 20 % and more usually at least about 30 %, and in many embodiments at least about 35 %, usually at least about 40% and more usually at least about 60 % amino acid sequence identity to the protein of the subject invention, as determined using MegAlign, DNASTar (1998) clustal algorithm as described in D. G. Higgins and P.M. Sharp, "Fast and Sensitive multiple Sequence Alignments on a Microcomputer," (1989) CABIOS, 5: 151-153. (Parameters used are ktuple 1, gap penalty 3, window, 5 and diagonals saved 5). In many embodiments, homologues of interest have much higher sequence identity, e.g., 65%, 70%, 75%, 80%, 85%, 90% or higher.

Also provided are proteins that are substantially identical to the wild type protein, where by substantially identical is meant that the protein has an amino acid sequence identity to the sequence of wild type protein of at least about 60%, usually at least about 65% and more usually at least about 70 %, where in some instances the identity may be much higher, e.g., 75%, 80%, 85%, 90%, 95% or higher.

In many embodiments, the subject homologues have structural features found in the above provided specific sequences, where such structural features include the β -can fold.

Proteins which are mutants of the above-described naturally occurring proteins are also provided. Mutants may retain biological properties of the wild-type (e.g., naturally occurring) proteins, or may have biological properties which differ from the wild-type proteins. The term "biological property" of the subject proteins includes, but is not limited to, spectral properties, such as absorbance maximum, emission maximum, maximum extinction coefficient, brightness (e.g., as compared to the wild-type protein or another reference

protein such as green fluorescent protein from *A. victoria*), and the like; *in vivo* and/or *in vitro* stability (e.g., half-life); etc. Mutants include single amino acid changes, deletions of one or more amino acids, N-terminal truncations, C-terminal truncations, insertions, etc.

5 Mutants can be generated using standard techniques of molecular biology, e.g., random mutagenesis, and targeted mutagenesis. Several mutants are described herein. Given the guidance provided in the Examples, and using standard techniques, those skilled in the art can readily generate a wide variety of additional mutants and test whether a biological property has been altered. For example, fluorescence intensity can be measured using a spectrophotometer at various excitation wavelengths.

10 Those proteins of the subject invention that are naturally occurring proteins are present in a non-naturally occurring environment, e.g., are separated from their naturally occurring environment. In certain embodiments, the subject proteins are present in a composition that is enriched for the subject protein as compared to its naturally occurring environment. For example, purified protein is provided, where by purified is meant that the protein is present in a composition that is substantially free of non-Anthozoa chromo/fluoroprotein derived proteins, where by substantially free is meant that less than 90 %, usually less
15 than 60 % and more usually less than 50 % of the composition is made up of non-Anthozoa derived chromoproteins or mutants thereof. The proteins of the subject invention may also be present as an isolate, by which is meant that the protein is substantially free of other proteins and other naturally occurring biologic molecules, such as oligosaccharides, polynucleotides and fragments thereof, and the like, where the term "substantially free" in this instance means that less than 70 %, usually less than 60% and more usually less
20 than 50 % of the composition containing the isolated protein is some other naturally occurring biological molecule. In certain embodiments, the proteins are present in substantially pure form, where by "substantially pure form" is meant at least 95%, usually at least 97% and more usually at least 99% pure.

In addition to the naturally occurring proteins, polypeptides which vary from the naturally occurring proteins, e.g., the mutant proteins described above, are also provided. Generally such polypeptides include an
25 amino acid sequence encoded by an open reading frame (ORF) of the gene encoding an Anthozoa protein, including the full length protein and fragments thereof, particularly biologically active fragments and/or fragments corresponding to functional domains, e.g., transmembrane domain, and the like; and including fusions of the subject polypeptides to other proteins or parts thereof. Fragments of interest will typically be at least about 10 aa in length, usually at least about 50 aa in length, and may be as long as 300 aa in length or
30 longer, but will usually not exceed about 1000 aa in length, where the fragment will have a stretch of amino acids that is identical to the subject protein of at least about 10 aa, and usually at least about 15 aa, and in many embodiments at least about 50 aa in length. In some embodiments, the subject polypeptides are about 25 aa, about 50 aa, about 75 aa, about 100 aa, about 125 aa, about 150 aa, about 200 aa, about 210 aa, about 220 aa, about 230 aa, or about 240 aa in length, up to the entire protein. In some embodiments, a
35 protein fragment retains all or substantially all of a biological property of the wild-type protein.

The subject proteins and polypeptides may be obtained from naturally occurring sources or synthetically produced. For example, wild type proteins may be derived from biological sources which express

- the proteins, e.g., Anthozoa species, such as the specific ones listed above. The subject proteins may also be derived from synthetic means, e.g. by expressing a recombinant gene or nucleic acid coding sequence encoding the protein of interest in a suitable host, as described above. Any convenient protein purification procedures may be employed, where suitable protein purification methodologies are described in Guide to Protein Purification, (Deuthser ed.) (Academic Press, 1990). For example, a lysate may prepared from the original source and purified using HPLC, exclusion chromatography, gel electrophoresis, affinity chromatography, and the like.

ANTIBODY COMPOSITIONS

- Also provided are antibodies that specifically bind to the subject fluorescent proteins. Suitable antibodies are obtained by immunizing a host animal with peptides comprising all or a portion of the subject protein. Suitable host animals include mouse, rat sheep, goat, hamster, rabbit, *etc.* The origin of the protein immunogen will generally be an Anthozoa species. The host animal will generally be a different species than the immunogen, e.g., mice, *etc.*
- The immunogen may comprise the complete protein, or fragments and derivatives thereof. Preferred immunogens comprise all or a part of the protein, where these residues contain the post-translation modifications found on the native target protein. Immunogens are produced in a variety of ways known in the art, e.g., expression of cloned genes using conventional recombinant methods, isolation from Anthozoa species, *etc.*
- For preparation of polyclonal antibodies, the first step is immunization of the host animal with the target protein, where the target protein will preferably be in substantially pure form, comprising less than about 1% contaminant. The immunogen may comprise the complete target protein, fragments or derivatives thereof. To increase the immune response of the host animal, the target protein may be combined with an adjuvant, where suitable adjuvants include alum, dextran, sulfate, large polymeric anions, oil & water emulsions, e.g. Freund's adjuvant, Freund's complete adjuvant, and the like. The target protein may also be conjugated to synthetic carrier proteins or synthetic antigens. A variety of hosts may be immunized to produce the polyclonal antibodies. Such hosts include rabbits, guinea pigs, rodents, e.g. mice, rats, sheep, goats, and the like. The target protein is administered to the host, usually intradermally, with an initial dosage followed by one or more, usually at least two, additional booster dosages. Following immunization, the blood from the host will be collected, followed by separation of the serum from the blood cells. The Ig present in the resultant antiserum may be further fractionated using known methods, such as ammonium salt fractionation, DEAE chromatography, and the like.
- Monoclonal antibodies are produced by conventional techniques. Generally, the spleen and/or lymph nodes of an immunized host animal provide a source of plasma cells. The plasma cells are immortalized by fusion with myeloma cells to produce hybridoma cells. Culture supernatant from individual hybridomas is screened using standard techniques to identify those producing antibodies with the desired specificity. Suitable animals for production of monoclonal antibodies to the human protein include mouse, rat, hamster,

etc. To raise antibodies against the mouse protein, the animal will generally be a hamster, guinea pig, rabbit, *etc.* The antibody may be purified from the hybridoma cell supernatants or ascites fluid by conventional techniques, *e.g.* affinity chromatography using protein bound to an insoluble support, protein A sepharose, *etc.*

- 5 The antibody may be produced as a single chain, instead of the normal multimeric structure. Single chain antibodies are described in Jost *et al.* (1994) J.B.C. 269:26267-73, and others. DNA sequences encoding the variable region of the heavy chain and the variable region of the light chain are ligated to a spacer encoding at least about 4 amino acids of small neutral amino acids, including glycine and/or serine. The protein encoded by this fusion allows assembly of a functional variable region that retains the specificity and affinity of the original antibody.
- 10

- Also of interest in certain embodiments are humanized antibodies. Methods of humanizing antibodies are known in the art. The humanized antibody may be the product of an animal having transgenic human immunoglobulin constant region genes (see for example International Patent Applications WO 90/10077 and WO 90/04036). Alternatively, the antibody of interest may be engineered by recombinant DNA techniques to substitute the CH1, CH2, CH3, hinge domains, and/or the framework domain with the corresponding human sequence (see WO 92/02190).
- 15

- The use of Ig cDNA for construction of chimeric immunoglobulin genes is known in the art (Liu *et al.* (1987) P.N.A.S. 84:3439 and (1987) J. Immunol. 139:3521). mRNA is isolated from a hybridoma or other cell producing the antibody and used to produce cDNA. The cDNA of interest may be amplified by the polymerase chain reaction using specific primers (U.S. Patent nos. 4,683,195 and 4,683,202). Alternatively, a library is made and screened to isolate the sequence of interest. The DNA sequence encoding the variable region of the antibody is then fused to human constant region sequences. The sequences of human constant regions genes may be found in Kabat *et al.* (1991) Sequences of Proteins of Immunological Interest, N.I.H. publication no. 91-3242. Human C region genes are readily available from known clones. The choice of isotype will be guided by the desired effector functions, such as complement fixation, or activity in antibody-dependent cellular cytotoxicity. Preferred isotypes are IgG1, IgG3 and IgG4. Either of the human light chain constant regions, kappa or lambda, may be used. The chimeric, humanized antibody is then expressed by conventional methods.
- 20
- 25

- Antibody fragments, such as Fv, F(ab')₂ and Fab may be prepared by cleavage of the intact protein, *e.g.* by protease or chemical cleavage. Alternatively, a truncated gene is designed. For example, a chimeric gene encoding a portion of the F(ab')₂ fragment would include DNA sequences encoding the CH1 domain and hinge region of the H chain, followed by a translational stop codon to yield the truncated molecule.
- 30

- Consensus sequences of H and L J regions may be used to design oligonucleotides for use as primers to introduce useful restriction sites into the J region for subsequent linkage of V region segments to human C region segments. C region cDNA can be modified by site directed mutagenesis to place a restriction site at the analogous position in the human sequence.
- 35

Expression vectors include plasmids, retroviruses, YACs, EBV derived episomes, and the like. A convenient vector is one that encodes a functionally complete human CH or CL immunoglobulin sequence, with appropriate restriction sites engineered so that any VH or VL sequence can be easily inserted and expressed. In such vectors, splicing usually occurs between the splice donor site in the inserted J region and the splice acceptor site preceding the human C region, and also at the splice regions that occur within the human CH exons. Polyadenylation and transcription termination occur at native chromosomal sites downstream of the coding regions. The resulting chimeric antibody may be joined to any strong promoter, including retroviral LTRs, e.g. SV-40 early promoter, (Okayama *et al.* (1983) Mol. Cell. Bio. 3:280), Rous sarcoma virus LTR (Gorman *et al.* (1982) P.N.A.S. 79:6777), and moloney murine leukemia virus LTR (Grosschedl *et al.* (1985) Cell 41:885); native Ig promoters, *etc.*

TRANSGENICS

The subject nucleic acids can be used to generate transgenic, non-human plants or animals or site specific gene modifications in cell lines. Transgenic cells of the subject invention include on or more nucleic acids according to the subject invention present as a transgene, where included within this definition are the parent cells transformed to include the transgene and the progeny thereof. In many embodiments, the transgenic cells are cells that do not normally harbor or contain a nucleic acid according to the subject invention. In those embodiments where the transgenic cells do naturally contain the subject nucleic acids, the nucleic acid will be present in the cell in a position other than its natural location, i.e. integrated into the genomic material of the cell at a non-natural location. Transgenic animals may be made through homologous recombination, where the endogenous locus is altered. Alternatively, a nucleic acid construct is randomly integrated into the genome. Vectors for stable integration include plasmids, retroviruses and other animal viruses, YACs, and the like.

Transgenic organisms of the subject invention include cells and multicellular organisms, e.g., plants and animals, that are endogenous knockouts in which expression of the endogenous gene is at least reduced if not eliminated. Transgenic organisms of interest also include cells and multicellular organisms, e.g., plants and animals, in which the protein or variants thereof is expressed in cells or tissues where it is not normally expressed and/or at levels not normally present in such cells or tissues.

DNA constructs for homologous recombination will comprise at least a portion of the gene of the subject invention, wherein the gene has the desired genetic modification(s), and includes regions of homology to the target locus. DNA constructs for random integration need not include regions of homology to mediate recombination. Conveniently, markers for positive and negative selection are included. Methods for generating cells having targeted gene modifications through homologous recombination are known in the art. For various techniques for transfecting mammalian cells, see Keown *et al.* (1990), Meth. Enzymol. 185:527-537.

For embryonic stem (ES) cells, an ES cell line may be employed, or embryonic cells may be obtained freshly from a host, e.g. mouse, rat, guinea pig, *etc.* Such cells are grown on an appropriate fibroblast-feeder

layer or grown in the presence of leukemia inhibiting factor (LIF). When ES or embryonic cells have been transformed, they may be used to produce transgenic animals. After transformation, the cells are plated onto a feeder layer in an appropriate medium. Cells containing the construct may be detected by employing a selective medium. After sufficient time for colonies to grow, they are picked and analyzed for the occurrence of homologous recombination or integration of the construct. Those colonies that are positive may then be used for embryo manipulation and blastocyst injection. Blastocysts are obtained from 4 to 6 week old superovulated females. The ES cells are trypsinized, and the modified cells are injected into the blastocoel of the blastocyst. After injection, the blastocysts are returned to each uterine horn of pseudopregnant females. Females are then allowed to go to term and the resulting offspring screened for the construct. By providing for a different phenotype of the blastocyst and the genetically modified cells, chimeric progeny can be readily detected.

The chimeric animals are screened for the presence of the modified gene and males and females having the modification are mated to produce homozygous progeny. If the gene alterations cause lethality at some point in development, tissues or organs can be maintained as allogeneic or congenic grafts or transplants, or in *in vitro* culture. The transgenic animals may be any non-human mammal, such as laboratory animals, domestic animals, etc. The transgenic animals may be used in functional studies, drug screening, etc. Representative examples of the use of transgenic animals include those described infra.

Transgenic plants may be produced in a similar manner. Methods of preparing transgenic plant cells and plants are described in U.S. Pat. Nos. 5,767,367; 5,750,870; 5,739,409; 5,689,049; 5,689,045; 5,674,731; 5,656,466; 5,633,155; 5,629,470; 5,595,896; 5,576,198; 5,538,879; 5,484,956; the disclosures of which are herein incorporated by reference. Methods of producing transgenic plants are also reviewed in Plant Biochemistry and Molecular Biology (eds Lea & Leegood, John Wiley & Sons)(1993) pp 275-295. In brief, a suitable plant cell or tissue is harvested, depending on the nature of the plant species. As such, in certain instances, protoplasts will be isolated, where such protoplasts may be isolated from a variety of different plant tissues, e.g. leaf, hypocotyl, root, etc. For protoplast isolation, the harvested cells are incubated in the presence of cellulases in order to remove the cell wall, where the exact incubation conditions vary depending on the type of plant and/or tissue from which the cell is derived. The resultant protoplasts are then separated from the resultant cellular debris by sieving and centrifugation. Instead of using protoplasts, embryogenic explants comprising somatic cells may be used for preparation of the transgenic host. Following cell or tissue harvesting, exogenous DNA of interest is introduced into the plant cells, where a variety of different techniques are available for such introduction. With isolated protoplasts, the opportunity arise for introduction via DNA-mediated gene transfer protocols, including: incubation of the protoplasts with naked DNA, e.g. plasmids, comprising the exogenous coding sequence of interest in the presence of polyvalent cations, e.g. PEG or PLO; and electroporation of the protoplasts in the presence of naked DNA comprising the exogenous sequence of interest. Protoplasts that have successfully taken up the exogenous DNA are then selected, grown into a callus, and ultimately into a transgenic plant through contact with the appropriate amounts and ratios of stimulatory factors, e.g. auxins and cytokinins. With embryogenic explants, a

convenient method of introducing the exogenous DNA in the target somatic cells is through the use of particle acceleration or "gene-gun" protocols. The resultant explants are then allowed to grow into chimera plants, cross-bred and transgenic progeny are obtained. Instead of the naked DNA approaches described above, another convenient method of producing transgenic plants is *Agrobacterium* mediated transformation. With

5 *Agrobacterium* mediated transformation, co-integrative or binary vectors comprising the exogenous DNA are prepared and then introduced into an appropriate *Agrobacterium* strain, e.g. *A. tumefaciens*. The resultant bacteria are then incubated with prepared protoplasts or tissue explants, e.g. leaf disks, and a callus is produced. The callus is then grown under selective conditions, selected and subjected to growth media to induce root and shoot growth to ultimately produce a transgenic plant.

10

UTILITY

The subject chromoproteins and fluorescent mutants thereof find use in a variety of different applications, where the applications necessarily differ depending on whether the protein is a chromoprotein or a fluorescent protein. Representative uses for each of these types of proteins will be described below, where

15 the follow described uses are merely representative and are in no way meant to limit the use of the subject proteins to those described below.

Chromoproteins

The subject chromoproteins of the present invention find use in a variety of different applications.

20 One application of interest is the use of the subject proteins as coloring agents which are capable of imparting color or pigment to a particular composition of matter. Of particular interest in certain embodiments are non-toxic chromoproteins. The subject chromoproteins may be incorporated into a variety of different compositions of matter, where representative compositions of matter include: food compositions, pharmaceuticals, cosmetics, living organisms, e.g., animals and plants, and the like. Where used as a coloring

25 agent or pigment, a sufficient amount of the chromoprotein is incorporated into the composition of matter to impart the desired color or pigment thereto. The chromoprotein may be incorporated into the composition of matter using any convenient protocol, where the particular protocol employed will necessarily depend, at least in part, on the nature of the composition of matter to be colored. Protocols that may be employed include, but are not limited to: blending, diffusion, friction, spraying, injection, tattooing, and the like.

30 The chromoproteins may also find use as labels in analyte detection assays, e.g., assays for biological analytes of interest. For example, the chromoproteins may be incorporated into adducts with analyte specific antibodies or binding fragments thereof and subsequently employed in immunoassays for analytes of interest in a complex sample, as described in U.S. Patent No. 4,302,536; the disclosure of which is herein incorporated by reference. Instead of antibodies or binding fragments thereof, the subject chromoproteins or

35 chromogenic fragments thereof may be conjugated to ligands that specifically bind to an analyte of interest, or other moieties, growth factors, hormones, and the like; as is readily apparent to those of skill in the art.

In yet other embodiments, the subject chromoproteins may be used as selectable markers in recombinant DNA applications, e.g., the production of transgenic cells and organisms, as described above. As such, one can engineer a particular transgenic production protocol to employ expression of the subject chromoproteins as a selectable marker, either for a successful or unsuccessful protocol. Thus, appearance of the color of the subject chromoprotein in the phenotype of the transgenic organism produced by a particular process can be used to indicate that the particular organism successfully harbors the transgene of interest, often integrated in a manner that provides for expression of the transgene in the organism. When used a selectable marker, a nucleic acid encoding for the subject chromoprotein can be employed in the transgenic generation process, where this process is described in greater detail supra. Particular transgenic organisms of interest where the subject proteins may be employed as selectable markers include transgenic plants, animals, bacteria, fungi, and the like.

In yet other embodiments, the chromoproteins (and fluorescent proteins) of the subject invention find use in sunscreens, as selective filters, etc., in a manner similar to the uses of the proteins described in WO 00/46233.

Fluorescent Proteins

The subject fluorescent proteins of the present invention (as well as other components of the subject invention described above) find use in a variety of different applications, where such applications include, but are not limited to, the following. The first application of interest is the use of the subject proteins in fluorescence resonance energy transfer (FRET) applications. In these applications, the subject proteins serve as donor and/or acceptors in combination with a second fluorescent protein or dye, e.g., a fluorescent protein as described in Matz et al., Nature Biotechnology (October 1999) 17:969-973, a green fluorescent protein from *Aequoria victoria* or fluorescent mutant thereof, e.g., as described in U.S. Patent No. 6,066,476; 6,020,192; 5,985,577; 5,976,796; 5,968,750; 5,968,738; 5,958,713; 5,919,445; 5,874,304, the disclosures of which are herein incorporated by reference, other fluorescent dyes, e.g., coumarin and its derivatives, e.g. 7-amino-4-methylcoumarin, aminocoumarin, bodipy dyes, such as Bodipy FL, cascade blue, fluorescein and its derivatives, e.g. fluorescein isothiocyanate, Oregon green, rhodamine dyes, e.g. texas red, tetramethylrhodamine, eosins and erythrosins, cyanine dyes, e.g. Cy3 and Cy5, macrocyclic chelates of lanthanide ions, e.g. quantum dye, etc., chemiluminescent dyes, e.g., luciferases, including those described in U.S. Patent Nos. 5,843,746; 5,700,673; 5,674,713; 5,618,722; 5,418,155; 5,330,906; 5,229,285; 5,221,623; 5,182,202; the disclosures of which are herein incorporated by reference. Specific examples of where FRET assays employing the subject fluorescent proteins may be used include, but are not limited to: the detection of protein-protein interactions, e.g., mammalian two-hybrid system, transcription factor dimerization, membrane protein multimerization, multiprotein complex formation, etc., as a biosensor for a number of different events, where a peptide or protein covalently links a FRET fluorescent combination including the subject fluorescent proteins and the linking peptide or protein is, e.g., a protease specific substrate, e.g., for caspase mediated cleavage, a linker that undergoes conformational change upon receiving a signal which increases or decreases

FRET, e.g., PKA regulatory domain (cAMP-sensor), phosphorylation, e.g., where there is a phosphorylation site in the linker or the linker has binding specificity to phosphorylated/dephosphorylated domain of another protein, or the linker has Ca^{2+} binding domain. Representative fluorescence resonance energy transfer or FRET applications in which the subject proteins find use include, but are not limited to, those described in:

5 U.S. Patent Nos. 6,008,373; 5,998,146; 5,981,200; 5,945,526; 5,945,283; 5,911,952; 5,869,255; 5,866,336; 5,863,727; 5,728,528; 5,707,804; 5,688,648; 5,439,797; the disclosures of which are herein incorporated by reference.

The subject fluorescent proteins also find use as biosensors in prokaryotic and eukaryotic cells, e.g. as Ca^{2+} ion indicator, as pH indicator, as phosphorylation indicator, as an indicator of other ions, e.g.,

10 magnesium, sodium, potassium, chloride and halides. For example, for detection of Ca ion, proteins containing an EF-hand motif are known to translocate from the cytosol to membranes upon Ca^{2+} binding. These proteins contain a myristoyl group that is buried within the molecule by hydrophobic interactions with other regions of the protein. Binding of Ca^{2+} induces a conformational change exposing the myristoyl group which then is available for the insertion into the lipid bilayer (called a " Ca^{2+} -myristoyl switch"). Fusion of

15 such a EF-hand containing protein to Fluorescent Proteins (FP) could make it an indicator of intracellular Ca^{2+} by monitoring the translocation from the cytosol to the plasma membrane by confocal microscopy. EF-hand proteins suitable for use in this system include, but are not limited to: recoverin (1-3), calcineurin B, troponin C, visinin, neurocalcin, calmodulin, parvalbumin, and the like. For pH, a system based on hisactophilins may be employed. Hisactophilins are myristoylated histidine-rich proteins known to exist in

20 *Dictyostelium*. Their binding to actin and acidic lipids is sharply pH-dependent within the range of cytoplasmic pH variations. In living cells membrane binding seems to override the interaction of hisactophilins with actin filaments. At $\text{pH} \leq 6.5$ they locate to the plasma membrane and nucleus. In contrast, at $\text{pH} 7.5$ they evenly distribute throughout the cytoplasmic space. This change of distribution is reversible and is attributed to histidine clusters exposed in loops on the surface of the molecule. The reversion of intracellular distribution

25 in the range of cytoplasmic pH variations is in accord with a pK of 6.5 of histidine residues. The cellular distribution is independent of myristoylation of the protein. By fusing FPs (Fluorescent Proteins) to hisactophilin the intracellular distribution of the fusion protein can be followed by laser scanning, confocal microscopy or standard fluorescence microscopy. Quantitative fluorescence analysis can be done by performing line scans through cells (laser scanning confocal microscopy) or other electronic data analysis

30 (e.g., using metamorph software (Universal Imaging Corp) and averaging of data collected in a population of cells. Substantial pH-dependent redistribution of hisactophilin-FP from the cytosol to the plasma membrane occurs within 1-2 min and reaches a steady state level after 5-10 min. The reverse reaction takes place on a similar time scale. As such, hisactophilin-fluorescent protein fusion protein that acts in an analogous fashion can be used to monitor cytosolic pH changes in real time in live mammalian cells. Such methods have use in

35 high throughput applications, e.g., in the measurement of pH changes as consequence of growth factor receptor activation (e.g. epithelial or platelet-derived growth factor) chemotactic stimulation/ cell locomotion, in the detection of intracellular pH changes as second messenger, in the monitoring of intracellular pH in pH

manipulating experiments, and the like. For detection of PKC activity, the reporter system exploits the fact that a molecule called MARCKS (myristoylated alanine-rich C kinase substrate) is a PKC substrate. It is anchored to the plasma membrane via myristoylation and a stretch of positively charged amino acids (ED-domain) that bind to the negatively charged plasma membrane via electrostatic interactions. Upon PKC activation the ED-domain becomes phosphorylated by PKC, thereby becoming negatively charged, and as a consequence of electrostatic repulsion MARCKS translocates from the plasma membrane to the cytoplasm (called the "myristoyl-electrostatic switch"). Fusion of the N-terminus of MARCKS ranging from the myristoylation motif to the ED-domain of MARCKS to fluorescent proteins of the present invention makes the above a detector system for PKC activity. When phosphorylated by PKC, the fusion protein translocates from the plasma membrane to the cytosol. This translocation is followed by standard fluorescence microscopy or confocal microscopy e.g. using the Cellomics technology or other High Content Screening systems (e.g. Universal Imaging Corp./Becton Dickinson). The above reporter system has application in High Content Screening, e.g., screening for PKC inhibitors, and as an indicator for PKC activity in many screening scenarios for potential reagents interfering with this signal transduction pathway. Methods of using fluorescent proteins as biosensors also include those described in U.S. Patent Nos. 972,638; 5,824,485 and 5,650,135 (as well as the references cited therein) the disclosures of which are herein incorporated by reference.

The subject fluorescent proteins also find use in applications involving the automated screening of arrays of cells expressing fluorescent reporting groups by using microscopic imaging and electronic analysis. Screening can be used for drug discovery and in the field of functional genomics: e.g., where the subject proteins are used as markers of whole cells to detect changes in multicellular reorganization and migration, e.g., formation of multicellular tubules (blood vessel formation) by endothelial cells, migration of cells through Fluoroblok Insert System (Becton Dickinson Co.), wound healing, neurite outgrowth, etc.; where the proteins are used as markers fused to peptides (e.g., targeting sequences) and proteins that allow the detection of change of intracellular location as indicator for cellular activity, for example: signal transduction, such as kinase and transcription factor translocation upon stimuli, such as protein kinase C, protein kinase A, transcription factor NFkB, and NFAT; cell cycle proteins, such as cyclin A, cyclin B1 and cyclinE; protease cleavage with subsequent movement of cleaved substrate, phospholipids, with markers for intracellular structures such as endoplasmic reticulum, Golgi apparatus, mitochondria, peroxisomes, nucleus, nucleoli, plasma membrane, histones, endosomes, lysosomes, microtubules, actin) as tools for High Content Screening: co-localization of other fluorescent fusion proteins with these localization markers as indicators of movements of intracellular fluorescent fusion proteins/peptides or as marker alone; and the like. Examples of applications involving the automated screening of arrays of cells in which the subject fluorescent proteins find use include: U.S. Patent No. 5,989,835; as well as WO/0017624; WO 00/26408; WO 00/17643; and WO 00/03246; the disclosures of which are herein incorporated by reference.

The subject fluorescent proteins also find use in high through-put screening assays. The subject fluorescent proteins are stable proteins with half-lives of more than 24h. Also provided are destabilized

versions of the subject fluorescent proteins with shorter half-lives that can be used as transcription reporters for drug discovery. For example, a protein according to the subject invention can be fused with a putative proteolytic signal sequence derived from a protein with shorter half-life, e.g., PEST sequence from the mouse ornithine decarboxylase gene, mouse cyclin B1 destruction box and ubiquitin, etc. Promoters in signal transduction pathways can be detected using destabilized versions of the subject fluorescent proteins for drug screening, e.g., AP1, NFAT, NFkB, Smad, STAT, p53, E2F, Rb, myc, CRE, ER, GR and TRE, and the like.

The subject proteins can be used as second messenger detectors, e.g., by fusing the subject proteins to specific domains: e.g., PKCgamma Ca binding domain, PKCgamma DAG binding domain, SH2 domain and SH3 domain, etc.

10 Secreted forms of the subject proteins can be prepared, e.g. by fusing secreted leading sequences to the subject proteins to construct secreted forms of the subject proteins, which in turn can be used in a variety of different applications.

The subject proteins also find use in fluorescence activated cell sorting applications. In such applications, the subject fluorescent protein is used as a label to mark a population of cells and the resulting labeled population of cells is then sorted with a fluorescent activated cell sorting device, as is known in the art. FACS methods are described in U.S. Patent Nos. 5,968,738 and 5,804,387; the disclosures of which are herein incorporated by reference.

The subject proteins also find use as in vivo marker in animals (e.g., transgenic animals). For example, expression of the subject protein can be driven by tissue specific promoters, where such methods find use in research for gene therapy, e.g., testing efficiency of transgenic expression, among other applications. A representative application of fluorescent proteins in transgenic animals that illustrates this class of applications of the subject proteins is found in WO 00/02997, the disclosure of which is herein incorporated by reference.

25 Additional applications of the subject proteins include: as markers following injection into cells or animals and in calibration for quantitative measurements (fluorescence and protein); as markers or reporters in oxygen biosensor devices for monitoring cell viability; as markers or labels for animals, pets, toys, food, etc.; and the like.

The subject fluorescent proteins also find use in protease cleavage assays. For example, cleavage inactivated fluorescence assays can be developed using the subject proteins, where the subject proteins are engineered to include a protease specific cleavage sequence without destroying the fluorescent character of the protein. Upon cleavage of the fluorescent protein by an activated protease fluorescence would sharply decrease due to the destruction of a functional chromophor. Alternatively, cleavage activated fluorescence can be developed using the subject proteins, where the subject proteins are engineered to contain an additional spacer sequence in close proximity/or inside the chromophor. This variant would be significantly decreased in its fluorescent activity, because parts of the functional chromophor would be divided by the spacer. The spacer would be framed by two identical protease specific cleavage sites. Upon cleavage via the activated protease the spacer would be cut out and the two residual "subunits" of the fluorescent protein would be able

to reassemble to generate a functional fluorescent protein. Both of the above types of application could be developed in assays for a variety of different types of proteases, e.g., caspases, etc.

The subject proteins can also be used in assays to determine the phospholipid composition in biological membranes. For example, fusion proteins of the subject proteins (or any other kind of covalent or non-covalent modification of the subject proteins) that allows binding to specific phospholipids to localize/visualize patterns of phospholipid distribution in biological membranes also allowing colocalization of membrane proteins in specific phospholipid rafts can be accomplished with the subject proteins. For example, the PH domain of GRP1 has a high affinity to phosphatidyl-inositol tri-phosphate (PIP3) but not to PIP2. As such, a fusion protein between the PH domain of GRP1 and the subject proteins can be constructed to specifically label PIP3 rich areas in biological membranes.

Yet another application of the subject proteins is as a fluorescent timer, in which the switch of one fluorescent color to another (e.g. green to red) concomitant with the ageing of the fluorescent protein is used to determine the activation/deactivation of gene expression, e.g., developmental gene expression, cell cycle dependent gene expression, circadian rhythm specific gene expression, and the like.

The antibodies of the subject invention, described above, also find use in a number of applications, including the differentiation of the subject proteins from other fluorescent proteins.

KITS

Also provided by the subject invention are kits for use in practicing one or more of the above described applications, where the subject kits include a chromo- or fluorescent protein according to the subject methods or a means for making the protein, e.g., a construct comprising a vector that includes a coding region for the subject protein. The protein or construct therefore is present in a suitable storage medium, e.g., buffered solution, typically in a suitable container. Also present in the subject kits may be antibodies to the provided protein. In certain embodiments, the kit comprises a plurality of different vectors each encoding the subject protein, where the vectors are designed for expression in different environments and/or under different conditions, e.g., constitutive expression where the vector includes a strong promoter for expression in mammalian cells, a promoterless vector with a multiple cloning site for custom insertion of a promoter and tailored expression, etc.

The following examples are offered by way of illustration and not by way of limitation.

EXPERIMENTAL

I. Wild-Type Anthozoa Proteins

The following table summarizes the properties of nine specific wild type anthozoa proteins of the subject invention:

TABLE I

NFP	Species	Identifier	Absorb. Max. Nm	Emission Max. Nm	Maximum Extinction Coeff.	Relative Quantum Yield*	Relative Brightness **
1	Anemonia majano	amFP486	458	486	40,000	0.3	0.43
2	Clavularia sp.	cFP484	456	484	35,300	0.6	0.77
3	Zoanthus sp.	zFP506	496	506	35,600	0.79	1.02
4	Zoanthus sp.	zFP538	528	538	20,200	0.52	0.38
5	Discosoma striata	dsFP483	443	483	23,900	0.57	0.50
6	Discosoma sp. "red"	drFP583	558	583	22,500	0.29	0.24
7	Anemonia sulcata	asFP600	572	596	56,200	<0.001	-
8	Discosoma sp "green"	dgFP512	502	512	20,360	0.3	0.21
9	Discosoma sp. "magenta"	dmFP592	573	593	21,800	0.11	0.09

*relative quantum yield was determined as compared to the quantum yield of *A. victoria* GFP.

**relative brightness is extinction coefficient multiplied by quantum yield divided by the same value for *A. victoria* GFP.

5

II. amFP486 Characterization and Mutants Thereof

A. Construction of amFP486 Mutants

Two mutants of amFP486 were generated, Mut15 and Mut32. Compared with wildtype amFP486, Mut15 has the following point mutations: A to G at position 101 (numbered from beginning of ATG); T to C at position 129; AAA to TTG at positions 202-204; C to T at position 240. Mut32 has two amino acid substitutions relative to the wildtype, i.e., Asn-34 to Ser; and Lys-68 to met. Table 2 lists the spectral properties of Mut15 and Mut32.

10

TABLE 2

Spectral Properties of the Isolated Mut15 and Mut32

Species	NFP Name	Absorbance Maximum nm	Emission Maximum nm	Maximum Extinction Coeff.	Quantum Yield	Relative Brightness *
Anemonia majano	Mut15	460	485	53,400	0.32	0.78
Anemonia majano	Mut32	466	488	36,000	0.42	0.69

15

*relative brightness is extinction coefficient multiplied by quantum yield divided by the same value for *A. victoria* GFP.

B. Construction and Functional Analysis of Vectors

Mut32 DNA was amplified via PCR and reconstructed to EGFP-N1 backbone with BamHI and NotI restriction enzyme sites. This vector has the same multiple cloning sites as EGFP-N1.

20

Functional tests of the generated vectors was performed by transient transfection in 293 cells. After 24-hour expression, brighter fluorescent intensity and less photobleaching of pCNFPMut32-N1 were observed by microscopy when compared with pECFP-N1 side by side.

- 5 Mut32 has fast folding and bright fluorescent intensity, which makes it useful for number of applications. Some fusion proteins were tested, such as PKC-gamma-CNFP. PKC was observed to translocate from cytosol to the plasma membrane when cells were treated with PMA (phorbol 12-myristate 13-acetate).

C. Generation of Destabilized amFP486 Vectors as Transcription Reporters

- 10 Three destabilized amFP486 vectors were constructed by fusing different mouse ODC degradation domains such as d1, d2 and d376 to the C-terminal of wild type amFP486. The vectors were constructed in EGFP-N1 backbone.

- Vectors of pCRE-d1CNFP and pNF- κ B-d1CNFP were constructed by placing d1CNFP downstream of cAMP response element (CRE) or NF- κ B response element, respectively. Expression of d1CNFP is up-regulated upon activation of these response elements.
- 15

D. Functional Analysis of Destabilized amFP486

- Functional tests of the destabilized amFP486 were performed by transient transfection in 293 cells. After 24-hour expression, the fluorescent intensity was decreased gradually from d2, d1 and d376 because of the fusion with different mouse ODC degradation domains. After 4-hour treatment with protein synthesis inhibitor cycloheximide, d2 fluorescent intensity did not change very much; however, d1 fluorescent intensity decreased further 50% of its original intensity. The half-life of d1 is around 4 hours.
- 20

- MODCdl is a valuable tool for application as a transcription reporter. However, compared with EGFP-d1 (1-hour half-life), pCNFP-MODCdl half-life (4 hours) is still long, so further mutagenesis for MODC degradation domain is still needed for shorter half-life version.
- 25

- Functional tests of vectors pCRE-d1CNFP and pNF- κ B-d1CNFP were performed by transient transfection in HEK 293 cells. 16 hours post transfection, 10 μ M forskolin was added to induce CRE and 100 ng/ml TNF-alpha was added to induce NF- κ B for 6 hours. Expression of d1CNFP was analysed using FACS Calibur. Up to 7 fold increase of fluorescence in forskolin induced CRE activation and 4 fold increase of fluorescence in TNF-alpha induced NF- κ B activation was observed (data not shown).
- 30

E. Construction and Functional Test for Humanized Mut32 (pCNFP-N1)

- Since mammalian expression is a very popular tool, human favored codon version is needed for better expression in mammalian cells. To generate humanized Mut32, the Mut 32 sequence was first changed to human favored codon and 23 oligos (12F and 11R) were designed. Next, four rounds of PCR amplification were performed, each round for 20 cycles. PCR cycle was designed as follows: 94°C for 1 min; 94°C for 1 min; 40°C for 1 min; and 72°C for 1 min. The four rounds were: for 1st round, mixing 2 μ l each of every 4
- 35

oligos (60 bp), 5 µl buffer, 1 µl pfu, 1 µl dNTP to make total volume of 50 µl. After 20 cycles of PCR, 5 sets of 150 bp and 1 set of 4 last oligos of 90 bp products were obtained. For 2nd round, mixing new crude PCR products 10 µl each, 5 µl buffer, 1 µl pfu, 1 µl dNTP to make total volume of 50 µl. After 20 cycles of PCR, 2 sets of 270 bp and 1 set of 210 bp PCR products were obtained. For 3rd round, mixing new crude PCR products. After 20 cycles of PCR, 1 set of 510 bp and 1 set of 450 bp products were obtained. For 4th round, mixing new crude products. After 20 cycles of PCR, final PCR product (690 bp) was obtained. Further PCR amplification was performed using 1F and 11R primers. As a result, humanized Mut32 was generated. This humanized Mut32 was constituted into EGFP-N1 backbone.

10 F. Expression of Wildtype and Mutant amFP486 in Mammalian Cells

The original plasmid amFP486 DNAs (wildtype, Mut15 and Mut32 in pQE30) were used to construct N1 version of amFP486 wildtype, Mut15 and Mut32 as described above. The DNAs were inserted into *E. coli* DH5α. HEK 293 cells were transferred with each of the three N1 constructs using Calcium Phosphate method (Clontech product #K2051-1).

15 The fluorescent intensity of the transfected cells was analyzed on FACS using FL1 (510/30) detecting channel. Five samples were analyzed in parallel for each construct. The observed mean value of FL1 fluorescent intensity of the M1 population of each sample is summarized in Table 3. It shows that the average of the mean value of each construct (Wildtype, Mut15, and Mut32) has no significant difference.

20

TABLE 3

FL1 Fluorescent Intensity of M1 Population

Sample #	Wildtype	Mut15	Mut32
1	82.84	106.95	84.51
2	77.52	108.73	91.41
3	111.85	97.08	91.30
4	113.06	90.16	98.16
5	104.95	86.34	111.44
Mean	98.04	97.85	95.36

G. Generation and Expression of Fusion Protein Mut15-mdm2

25 The Mut15-mdm2 fusion was generated by the following steps: first, mdm2 DNA was obtained by amplifying human Marathon cDNA library (Burke's Lymphoma) using primers:

ATGTGCAATACCAACATGTCTGTACC (SEQ ID No. 19) and

CTAGGGGAAATAAGTTAGCAC (SEQ ID No. 20); secondly, the purified PCR product was then amplified with primers:

GGAATTCAGCCATGGTGTGCAATACCAACATGTCTGTACC (SEQ ID No. 21) and

30 TCCCCCGGGGGGAAATAAGTTAGCAC (SEQ ID No. 22)

in order to add Kozac sequence and restriction sites; thirdly, the purified PCR product from step 2 was digested with EcoR I and Sma I and inserted into EcoR I and SmaI of NFP1Mut15-N1 vector (this vector was
